Description of Methods

Data for Lake Erie Metropark and Pointe Mouillee were grouped, sorted by date and time, and totaled. Site data and species data were then generated. Site data includes coverage by days and hours, and a summary table, with grand totals for all hawks. Analysis for each of 16 species includes Seasonal Occurrence, 3-Day Running Average, Day Statistics, Yearly Trends, and Trend Analysis.

Site Data

Coverage. The site data includes the number of days and the number of hours of coverage, presented by season in Figures 1 and 2 and by year in Figures 3 and 4. For each day from September 1 to November 30 the number of times that day was covered from 1991 to 2008 is indicated on [Figure 1](#), and the total number of hours in [Figure 2](#). For each year from 1991 to 2008, the number of days covered is indicated in [Figure 3](#) and the number of hours in [Figure 4](#). While coverage for the first 5 years shows no consistency, the coverage for 1996 to 2008 is consistent.

Summary Table. [Table 1](#) provides a concise summary of the combined data for Lake Erie Metropark and Pointe Mouillee. It includes annual data, grand totals, a comparison of the 2008 data to the 10 year average for 1998 to 2007, and a comparison of the 2009 data to the 10 year average for 1999 to 2008. Table 1 summarizes the annual counts for the 16 regularly occurring species, plus Black Vulture, which is gradually increasing in recent years. Also included are total hawks without Turkey Vultures, and total hawks without Turkey Vultures and without Broad-winged Hawks. This permits an overview of the total hawk movement past Detroit River without being overwhelmed by the very large numbers of Turkey Vultures and Broad-winged Hawks. (See [Figures 53](#) to 55 for graphs of these totals.) Table 1 also tabulates annual totals for the number of hours and days of coverage.

Species Data

Seasonal Occurrence. Seasonal Occurrence, computed separately for each of 16 species, includes a graph of the average number of that species seen on each day of the season for the years 1991 to 2008. The overall daily average number of hawks is noted as a horizontal line. The median date represents the middle of the flight period. On average, half the hawks are counted by this date. Since most species of hawks have flight periods that span fewer than the 91 days of coverage, the 90% passage was computed to better define that flight period. The period of 90% passage begins when 5% of the hawks have passed and ends when 95% have passed.

3-Day Running Average. The 3-Day Running Average, computed separately for each species, reduces the impact of factors other than the date that contribute to the count on a particular day. Since large flights often occur on days of ideal weather, the daily averages plotted in the Seasonal Occurrence are influenced by those large numbers. However, it is unlikely that any date is more likely to have optimal conditions than the two adjacent dates. The 3-Day Running Average documents the number of hawks, while reducing the impact of single ideal days. The result is a smoother curve that more clearly shows the period when counts are consistently above average.

Day statistics. For each species, the Day Statistics are tabulated by date, 9/1 to 11/30, including the number of years that day was covered and the average, cumulative average, cumulative percent, and maximum number of hawks on that date. The cumulative average represents the average total number of hawks for the season, up to that date. The cumulative percent represents the average proportion of total hawks for the season, up to that date.

Yearly Trend. For each species, yearly totals are graphed for 1991 to 2008. Since coverage for 1996 through 2008 was comparable (Figures 3 and 4), linear regression for these years was computed for a 13 year trend. The regression coefficient on x can be interpreted as the annual increase (if positive) or decrease (if negative) in the number of hawks. R^2 is the coefficient of determination and can be loosely interpreted as the proportion of the variation in data that can be attributed to the passage of time. For example, there has been an increase of 12 Bald Eagles per year, with 0.69 or 69% of the variation explained by advancing years (Figure 13). This linear regression provides an overview of the observed trend. Specifics regarding significance of the regression are included in the trend analysis.

Trend Analysis

[Table 18](#) summarizes the linear regression analysis for the yearly trends of the 16 species of hawks. Regression analysis assumes a normal distribution about the resulting curve. Regarding normality, the table indicates the distribution for the data alone and also for the data about the regression line. Also included on this table is the regression coefficient on x and R^2 , as [described above](#), and the p value. The p value is the probability of being wrong in concluding that there is a significant trend: the smaller the p value, the greater the probability that there is a trend. A p value less than 0.05 is considered significant, offering a 95% confidence that the distribution did not occur purely by chance. For species for which data is not normally distributed about the regression line, the Spearman Rank Correlation was computed to assess the strength of a positive or negative relationship between the count and the passage of years. A correlation value close to one indicates a strong relationship, whereas a value close to zero indicates no relationship.

Table 18. Linear Regression and Rank Correlation for Yearly Trends, 1996-2008

Interpretation of Trend Analysis.

Three hawk species have significant or close to significant positive trends: Bald Eagle, Turkey Vulture, and Osprey. The Bald Eagle distribution meets all assumptions for regression and results in an increase of 12 eagles per year with 99.9% confidence ($p < 0.001$). The Turkey Vulture distribution fails to be normally distributed about the regression line, in spite of a $p < 0.001$. Spearman Rank Correlation, however, shows a strong positive relationship for Turkey Vultures at $p < 0.001$. Regression analysis for Osprey results in $p = 0.067$, very close to the $p = 0.05$ criteria for significance. All other p values were greater than 0.100, indicating no significant linear trend. For these species, we have insufficient evidence to indicate anything other than a random distribution of counts over time. This is reflected in the more or less horizontal regression lines for the Yearly Trends for many species.
